### Model Performance Testing:

The table below summarises my Employee Raise Issue system and how it went during testing, with a screenshot for each point.

| S.No. | Parameter | Values | Screenshot |
|---|---|---|---|
| 1. | System Summary | This project is an Employee Raise Issue system built on ServiceNow. An employee opens the Requesting portal, clicks *Raise Ticket* and fills in the *Raise Employee Issue* form (requester, category, subcategory, state and short description). On submit, a record is created in the *Employee raises issue* table. I added UI policies and a category-subcategory dependency to keep the entries clean. |  |
| 2. | Functional Accuracy | I checked the flow from the portal to the table. The portal and both widgets showed up, *Raise Ticket* opened the *Raise Employee Issue* form, and submitting it created record EMP0001009 with the requester, category and subcategory I selected. The Number field stayed read-only. |  |
| 3. | Performance Testing | While testing, I went through the portal home page, the widgets and the form. The page loaded with Recent Items and both widgets, the *Raise Ticket* button opened the form, and the submission created the record. No timing figures are quoted here. |  |
| 4. | User Acceptance Testing | I ran the complete flow: open the portal, click *Raise Ticket*, fill in the form and submit. It worked without any critical issues, and the end-to-end testing showed the solution to be stable and reliable. |  |
